Data Import and Transformation Documentation

1. Data SourceA. Folder Import. Sales data is imported from multiple Excel files located in the specified folder using `Folder.Files()`.
B. Hidden Files. Hidden/system files are excluded to ensure only relevant source files are processed.

2. Data PreparationA. Remove Unnecessary Columns. File metadata such as extension, access dates, attributes, and folder paths are removed.
B. Read Excel Data. Each Excel file is opened, and worksheet contents are extracted and expanded into a single table.
C. Promote Headers. The first row is promoted as column headers, and duplicate header rows from other files are removed.
D. File Name Handling. File names are retained in a clean "File Name" column for tracking data sources.

3. Data TransformationA. Data Types. Appropriate data types are assigned to IDs, dates, numeric fields, and text fields (e.g., order_id as integer, order_date as date, unit_price as number).
B. Sales Amount. A new column `amount` is created by multiplying `unit_price * quantity`.
C. Column Reduction. Unnecessary descriptive columns are removed, keeping only analytical fields required for reporting.

4. Data FilteringA. Header Rows. Duplicate header rows across files are excluded.
B. Final Output. The resulting table contains standardized, cleaned, and calculated sales transaction data, ready for Power BI analysis.
